

# 650 V GaNFast™ Power IC

QFN 5 x 6 mm

Simplified schematic

#### 1. Features

#### **GaNFast™ Power IC**

- Monolithically-integrated gate drive
- Wide logic input range with hysteresis
- 5 V / 15 V input-compatible
- Wide Vcc range (10 to 30 V)
- Programmable turn-on dV/dt
- 200 V/ns dV/dt immunity
- 650 V eMode GaN FET
- Low 170 mΩ resistance
- Zero reverse recovery charge
- 2 MHz operation

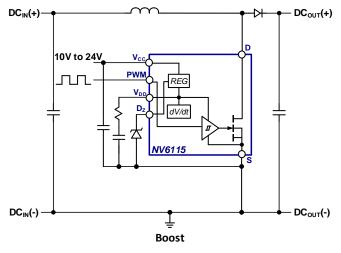

#### Small, low-profile SMT QFN

- 5 x 6 mm footprint, 0.85 mm profile
- · Minimized package inductance

#### **Environmental**

• RoHS, Pb-free, REACH-compliant

# 4. Typical Application Circuits

## 2. Description

The NV6115 is a 650 V GaNFast™ power IC, optimized for high frequency, soft-switching topologies.

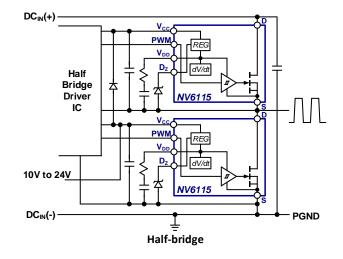

Monolithic integration of FET, drive and logic creates an easy-to-use 'digital-in, power-out' high-performance powertrain building block, enabling designers to create the fastest, smallest, most efficient integrated powertrain in the world.

The highest dV/dt immunity, high-speed integrated drive and industry-standard low-profile, low-inductance, 5 x 6 mm SMT QFN package allow designers to exploit Navitas GaN technology with simple, quick, dependable solutions for breakthrough power density and efficiency.

Navitas' GaNFast™ power ICs extend the capabilities of traditional topologies such as flyback, half-bridge, resonant, etc. to MHz+ and enable the commercial introduction of breakthrough designs.

## 3. Topologies / Applications

- AC-DC, DC-DC, DC-AC
- · Buck, boost, half bridge, full bridge
- Active Clamp Flyback, LLC resonant, Class D
- · Quasi-Resonant Flyback
- · Mobile fast-chargers, adapters
- Notebook adaptors
- · LED lighting, solar micro-inverters
- TV / monitor, wireless power
- Server, telecom & networking SMPS

# 8. Functional Description

The following functional description contains additional information regarding the IC operating modes and pin functionality.

### 8.1. Start Up

When the  $V_{CC}$  supply is first applied to the NV6115, care should be taken such that the  $V_{DD}$  and  $D_Z$  pins are up at their correct voltage levels before the PWM input signal starts. The  $V_{DD}$  pin ramp up time is determined by the internal regulator current at this pin and the external  $C_{VDD}$  capacitor. Also, since the  $D_Z$  pin voltage sets the  $V_{DD}$  voltage level, the  $V_{DD}$  pin will ramp up together with the  $D_Z$  pin (Fig. 18).

For half-bridge configurations, it is important that the V  $_{\rm CC}$  supply, the D  $_{\rm Z}$  pin, and the V  $_{\rm DD}$  supply of the high-side NV6115 are all charged up to their proper levels before the first high-side PWM pulses start. For LLC applications, a long on-time PWM pulse to the low-side (> 10  $\mu$ s) is typically provided by the LLC controller to allow the supply pins of the high-side NV6115 to charge up (through the external bootstrap diode) to their correct levels before the first high-side PWM pulses start (Fig. 19).

For active clamp flyback (ACF) applications, the half-bridge must be ready very quickly due to the soft-start mode of the ACF controller. When the first few PWM pulses are generated by the ACF controller, the high-side supply pins of the NV6115 will require a few low-side pulses to charge up (through the external bootstrap diode) before the high-side starts to switch (Fig. 20).

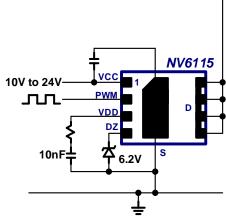

Fig. 18. Quick start-up circuit

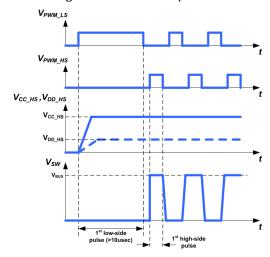

Fig. 19. LLC half-bridge start-up timing diagram

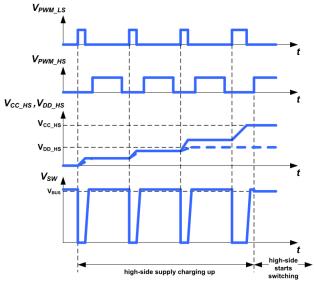

Fig. 20. ACF half-bridge start-up timing diagram

### 8.2. Normal Operating Mode

During Normal Operating Mode, all of the internal circuit blocks are active.  $V_{CC}$  is operating within the recommended range of 10 V to 24 V, the  $V_{DD}$  pin is at the voltage set by the Zener diode at the  $D_Z$  pin (6.2 V), and the internal gate drive and power FET are both enabled. The external PWM signal at the PWM pin determines the frequency and duty-cycle of the internal gate of the power FET. As the PWM voltage toggles above and below the rising and falling input thresholds (4 V and 1 V), the internal gate of the power FET toggles on and off between  $V_{DD}$  and 0 V (Fig. 21). The drain of the power FET then toggles between the source voltage (typically power ground) and a higher voltage level (650 V max), depending on the external power conversion circuit topology.

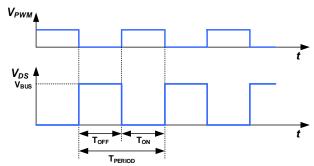

Fig. 21. Normal operating mode timing diagram

## 8.3. Standby Mode

For applications where a low standby power is required, an external series cut-off circuit (Fig. 22) can be used to disconnect V<sub>CC</sub> of the NV6115 from the main V<sub>CC</sub> supply of the power supply. This will reduce V<sub>CC</sub> current consumption when the converter is in burst mode during light-load or open load conditions. The V<sub>CC</sub> cut-off circuit consists of a series PMOS FET that is turned on and off with a pull-down NMOS FET. The gate of the NMOS is controlled by an external ENABLE signal that should be provided by the main controller of the power supply. The capacitor value at the V<sub>CC</sub> pin should then be selected according to the desired start-up speed of the NV6115 each time the ENABLE signal toggles high. A 22 nF capacitor at V<sub>CC</sub>, for example, will give a typical start-up time of approximately 2  $\mu$ s. An additional 200 k $\Omega$  resistor is placed across the PMOS cut-off FET to provide a small V<sub>CC</sub> voltage level for proper start-up.

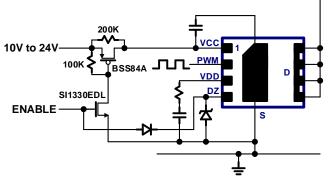

Fig. 22. Standby mode V<sub>CC</sub> cut-off circuit

### 8.4. Programmable Turn-on dV/dt Control

During first start-up pulses or during hard-switching conditions, it is desirable to limit the slew rate (dV/dt) of the drain of the power FET during turn-on. This is necessary to reduce EMI or reduce circuit switching noise. To program the turn-on dV/dt rate of the internal power FET, a resistor (R $_{\rm DD}$ ) is placed in between the V $_{\rm DD}$  capacitor and the V $_{\rm DD}$  pin. This resistor (R $_{\rm DD}$ ) sets the turn-on current of the internal gate driver and therefore sets the turn-on falling edge dV/dt rate of the drain of the power FET (Fig. 23). A typical turn-on slew-rate change with respect to R $_{\rm DD}$  is shown in Fig. 15.

#### Minimum 10 $\Omega$ R<sub>DD</sub> is required.

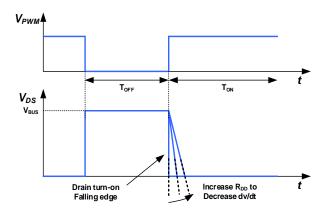

Fig. 23. Turn-on dV/dt slew rate control

Final Datasheet 12 Rev Nov 22, 2019

### 8.5. Current Sensing

For many applications it is necessary to sense the cycle-by-cycle current flowing through the power FET. To sense the current flowing through the NV6115, a standard current-sensing resistor can be placed in between the source and power ground (Fig. 24). In this configuration, all of the components around the NV6115 ( $C_{VCC}$ ,  $C_{VDD}$ ,  $D_{Z}$ , etc.) should be grounded with a single connection at the source. Also, an additional RC filter can be inserted between the PWM signal and the PWM pin (100  $\Omega$ , 100 pF typical). This filter is necessary to prevent false triggering due to high-frequency voltage spikes occurring at the source node due to external parasitic inductance from the source PCB trace or the current-sensing resistor itself.

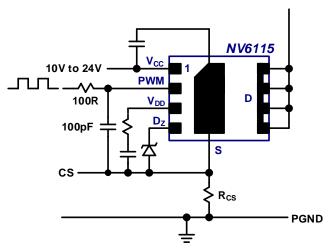

Fig. 24. Current sensing circuit

### 8.6. Paralleling Devices

For some applications it is desirable to parallel ICs in order to reduce conduction losses and temperatures. Two NV6115 ICs can be connected in parallel in a PFC boost application working in boundary-conduction mode (BCM) only. The parallel configuration for two NV6115 ICs is shown in Fig. 25. The paired pins that are connected together include the drain pins (D), the source pins (S), the  $V_{CC}$  pins, the PWM pins, and the  $D_7$ . A single  $D_7$  diode can be shared by both ICs. The  $V_{DD}$ pins are not connected together and require separate V<sub>DD</sub> supply capacitors (C<sub>VDD1</sub>, C<sub>VDD2</sub>) and separate turnon current set resistors (R<sub>DD1</sub>, R<sub>DD2</sub>). Each IC should have its own local Vcc supply filter capacitor (C<sub>VCC1</sub>, C<sub>VCC2</sub>). The PWM pins can have a single filter resistor  $(R_{PWM})$  but separate filter capacitors  $(C_{PWM1}, C_{PWM2})$ should be placed at the PWM pin of each IC. When designing the PCB layout for the two paralleled ICs, the drain and source connections should be made as symmetrical as possible to avoid any parasitic inductance or capacitance mismatch. A proper PCB layout example for paralleling is shown in Section 10.

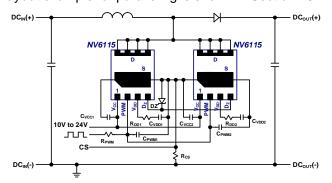

Fig. 25. Boost schematic using two parallel ICs

### 8.7. 3.3V PWM Input Circuit

For some applications where a 3.3 V PWM signal is required (DSP, MCU, etc.) an additional buffer can be placed before the PWM input pin (Fig. 26) with the buffer supply voltage connected to the  $V_{DD}$  capacitor.

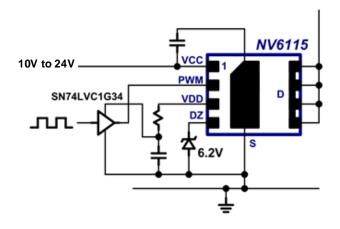

Fig. 26. 3.3 V PWM input buffer circuit

### 8.8. PCB Layout Guidelines

The design of the PCB layout is critical for good noise immunity, sufficient thermal management, and proper operation of the IC. Typical PCB layout examples for without current sensing resistor, with current sensing resistor, and paralleling, are all shown in Section 10.

The following rules should be followed carefully during the design of the PCB layout:

- Place all IC filter and programming components directly next to the IC. These components include (C<sub>VCC</sub>, C<sub>VDD</sub>, R<sub>PWM</sub>, C<sub>PWM</sub>, R<sub>DD</sub> and D<sub>7</sub>).
- 2) Keep ground trace of IC filter and programming components separate from power GND trace. Do not run power GND currents through ground trace of filter components!
- 3) For best thermal management, place thermal vias in the source pad area to conduct the heat out through the bottom of the package and through the PCB board to other layers (see Section 10 for correct layout examples).
- 4) Use large PCB thermal planes (connected with thermal vias to the source pad) and additional PCB layers to reduce IC temperatures as much as possible (see Section 10 for correct layout examples).
- 5) For half-bridge layouts, do not extend copper planes from one IC across the components or pads of the other IC!
- 6) For high density designs, use a 4-layer PCB and 2 oz. copper to route signal connections. This allows layout to maintain large thermal copper planes and reduce power device temperature.

### 8.9. Recommended Component Values

The following table (Table I) shows the recommended component values for the external filter capacitors, Zener diode, and  $R_{DD}$  connected to the pins of this GaNFast power IC. These components should be placed as close as possible to the IC. Please see PCB Layout guidelines for more information. The Zener diode at the  $D_Z$  pin should be a low-current type with a flat Zener, and the min/max limits must be followed.  $R_{DD}$  must be a minimum of 10  $\Omega$  to ensure application and device robustness.

SYM	DESCRIPTION	MIN	TYP	MAX	UNITS
C <sub>vcc</sub>	Maximum V <sub>cc</sub> supply capacitor		0.1		μF
$C_{_{VDD}}$	V <sub>DD</sub> supply capacitor		0.01		μF
R <sub>DD</sub>	Gate drive turn-on current set resistor	10	25	200	Ω
$R_{_{PWM}}$	PWM filter resistor		100		Ω
$C_{_{PWM}}$	PWM filter capacitor		100		pF

Table I. Recommended component values.

#### 8.9.1. Zener Selection

The Zener voltage is a critical parameter that sets the internal reference for gate drive voltage and other circuitry. The Zener diode needs to be selected such that the voltage on the  $D_Z$  pin is within recommended operating conditions (5.8 V to 6.6 V) across operating temperature (-40°C to 125°C) and bias current (10  $\mu$ A to 1 mA). To ensure effective operation, the current vs. voltage characteristics of the Zener diode should be measured down to 10  $\mu$ A to ensure flat characteristics across the current operating range (10  $\mu$ A to 1 mA). The recommended part numbers meet these requirements (See Table II). If the Zener selected by user does not ensure that the voltage on the Zener pin is always within the recommended operating range, the functionality and reliability of the GaNFast power IC can be impacted.

Only the following Zener diodes are to be used (Table II).

SYM	DESCRIPTION	PART NO.	SUPPLIER	MIN	TYP	MAX	UNITS
		BZT52B6V2 RHG	Taiwan Semiconductor Corporation				
D_	D <sub>z</sub> V <sub>DD</sub> set Zener diode (D <sub>z</sub> pin)	MM3Z6V2ST1G	ON-Semiconductor	5.8	6.2	6.6	V
Z	DD Z ,	PDZ6.2B.115	Nexperia (NXP)	3.0	0.2	0.0	V
		PLVA662A.215	Nexperia (NXP)				
		LM3Z6V2T1	Leshan Radio Company				

Table II. Qualified Zener diode components

Final Datasheet 15 Rev Nov 22, 2019

An external resistor ( $\sim$ 47 k $\Omega$ ) between V<sub>CC</sub> and D<sub>Z</sub> can improve Zener voltage stability by adding bias current to the Zener pin to ensure the voltage on the D<sub>Z</sub> pin is always within the recommended operating range (Fig. 27). This will add  $\sim$ 200  $\mu$ A of quiescent current.

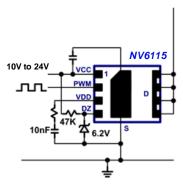

Fig. 27. Increasing Zener bias current for stable Zener voltage

## 8.10. GaN Power IC Drain-to-Source Voltage Design Considerations

For single ended topologies, such as quasi-resonant (QR) flyback, the drain-to-source voltage (V<sub>DS</sub>) of the GaN Power IC should be carefully designed in order to ensure there is sufficient derating to provide exceptional quality and long-term reliability. The different voltage stress levels found in a typical QR flyback topology can be analyzed using Fig. 28 as a reference. When the device is switched off each cycle, the energy stored in the transformer magnetizing and leakage inductances will cause the V<sub>DS</sub> to spike to the level of V<sub>SPIKE</sub>. The clamp circuit of the QR system should be designed such that V<sub>SPIKE</sub> stays below the Absolute Maximum rated V<sub>DS</sub> of 650 V on a cycle-bycycle basis in continuous operation. Following the dissipation of the spike energy due to the leakage inductance, the device V<sub>DS</sub> will be determined by the addition of the bus voltage (rectified AC input voltage) and the transformer reflected voltage which is defined in Fig. 28 as the V<sub>DS-OFF</sub>. To ensure sufficient design margin and long-term reliability, it is recommended to design the system such that V<sub>DS-OFF</sub> follows a typical derating of 80% from absolute maximum voltage. Finally, the transient drain to source voltage rating (V<sub>TDS</sub>) is provided in order to provide a margin for events that could occur on a non-repetitive basis, such as line surge due to lightning strikes. V<sub>TDS</sub> ensures excellent device robustness provided any non-repetitive drain-to-source voltages are maintained less than 750 V. For half-bridge based topologies, such as LLC or PFC, V<sub>DS</sub> voltage is clamped to the bus voltage. V<sub>DS</sub> should be designed such that it meets the V<sub>DS-OFF</sub> derating guideline. The V<sub>TDS</sub> of 750 V can also be used for non-repetitive events such as lightning surge.
